I. INTRODUCTION

This writing is continuation of the Phase I Report of the Ground Slide Airdrop Study, ER-3841. AAI has performed this study under Contract No. DA-19-129-AMC-337(N) from the U. S. Army Natick Laboratories. The specific object of this report is to present the findings of the Exploratory Test Phase, Phase II, and compare these actual findings to those predicted by the analysis presented in the Study Phase, Phase I. Also included in this report are all changes, deletions, and revisions to be incorporated in the preliminary design specifications of the Phase I report.

The actual findings were acquired from tests performed at Fort Bragg, North Carolina. These tests were conducted by AAI in conjunction with the U. S. Army Field Test Team. The test description and test program is explained in the Report of Exploratory Test Program, ER-4356. Figures 1, 2, 3, 4, and 5 show a typical drop sequence from an actual test. Table 1 lists tests with the associated test conditions.

B

II. PRESENTATION OF RESULTS

A. General

The results of the test program and the corresponding computer analysis for each test are presented in this section. These results are presented, for ease of handling, in three phases, i.e., Extraction and Tip-off, Descent, and Ground Impact.

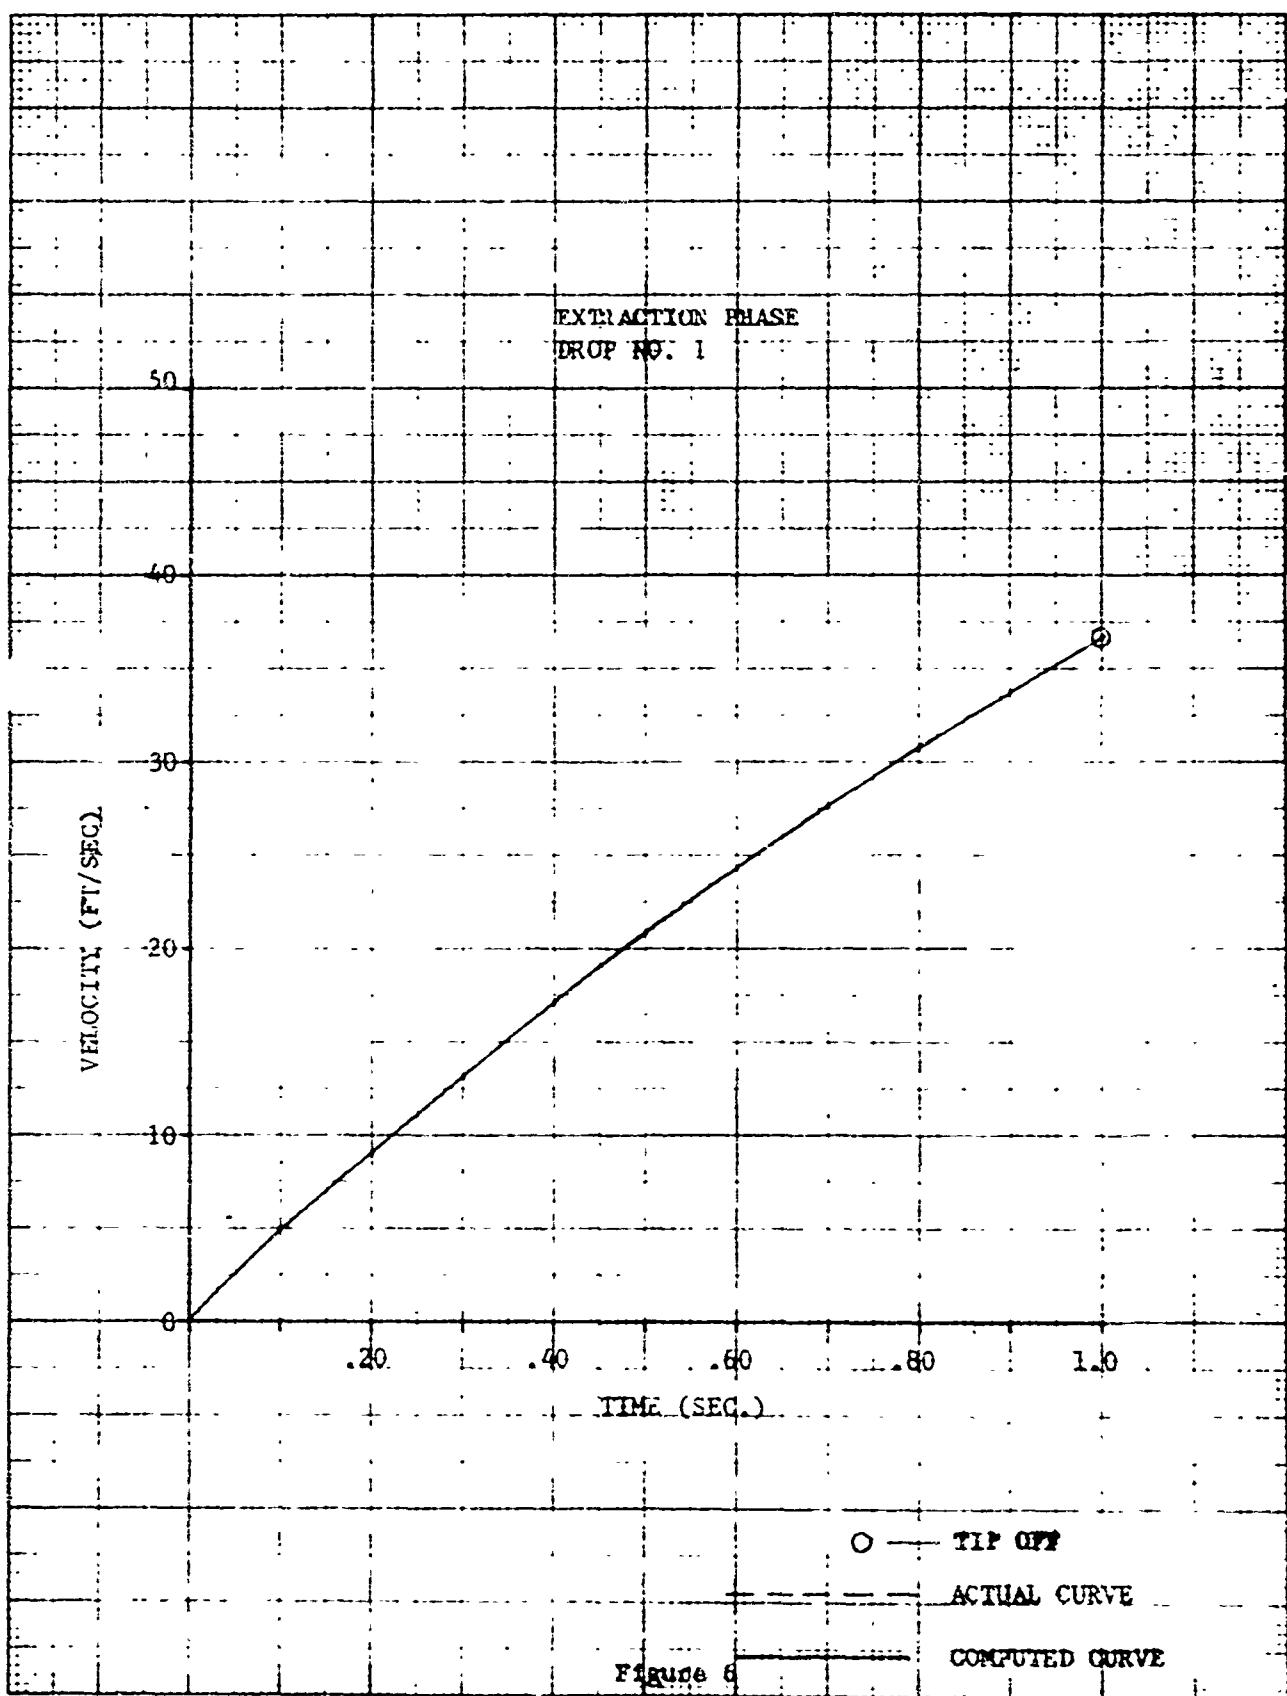

In each case the actual test conditions were used as inputs to the computer program and the computed values of velocity, time, distance, etc. are compared with the actual values. In general, the tests values and the computed values are in close agreement. The discrepancies that do occur can be attributed to (1) the inability of the equations of motion to account for all actual happenings such as initial cargo jerk due to restraint strap break and cargo angular acceleration after tip-off induced by aircraft pitching and (2) the inability to select the inputs for the computer with a high degree of accuracy.

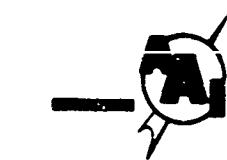

Drop No. 2 will not be presented because of camera failure.

B. Extraction Phase

The time-displacement recorder was used to monitor the relative velocity of the cargo with respect to the aircraft, during the extraction phase. The data obtained was reduced to velocity-versus-time curves. Figures 6 through 19 show plots comparing these actual curves to the curves predicted by the computer analysis. Drop Nos. 1, 4 and 7 are incomplete due to lack of test data.

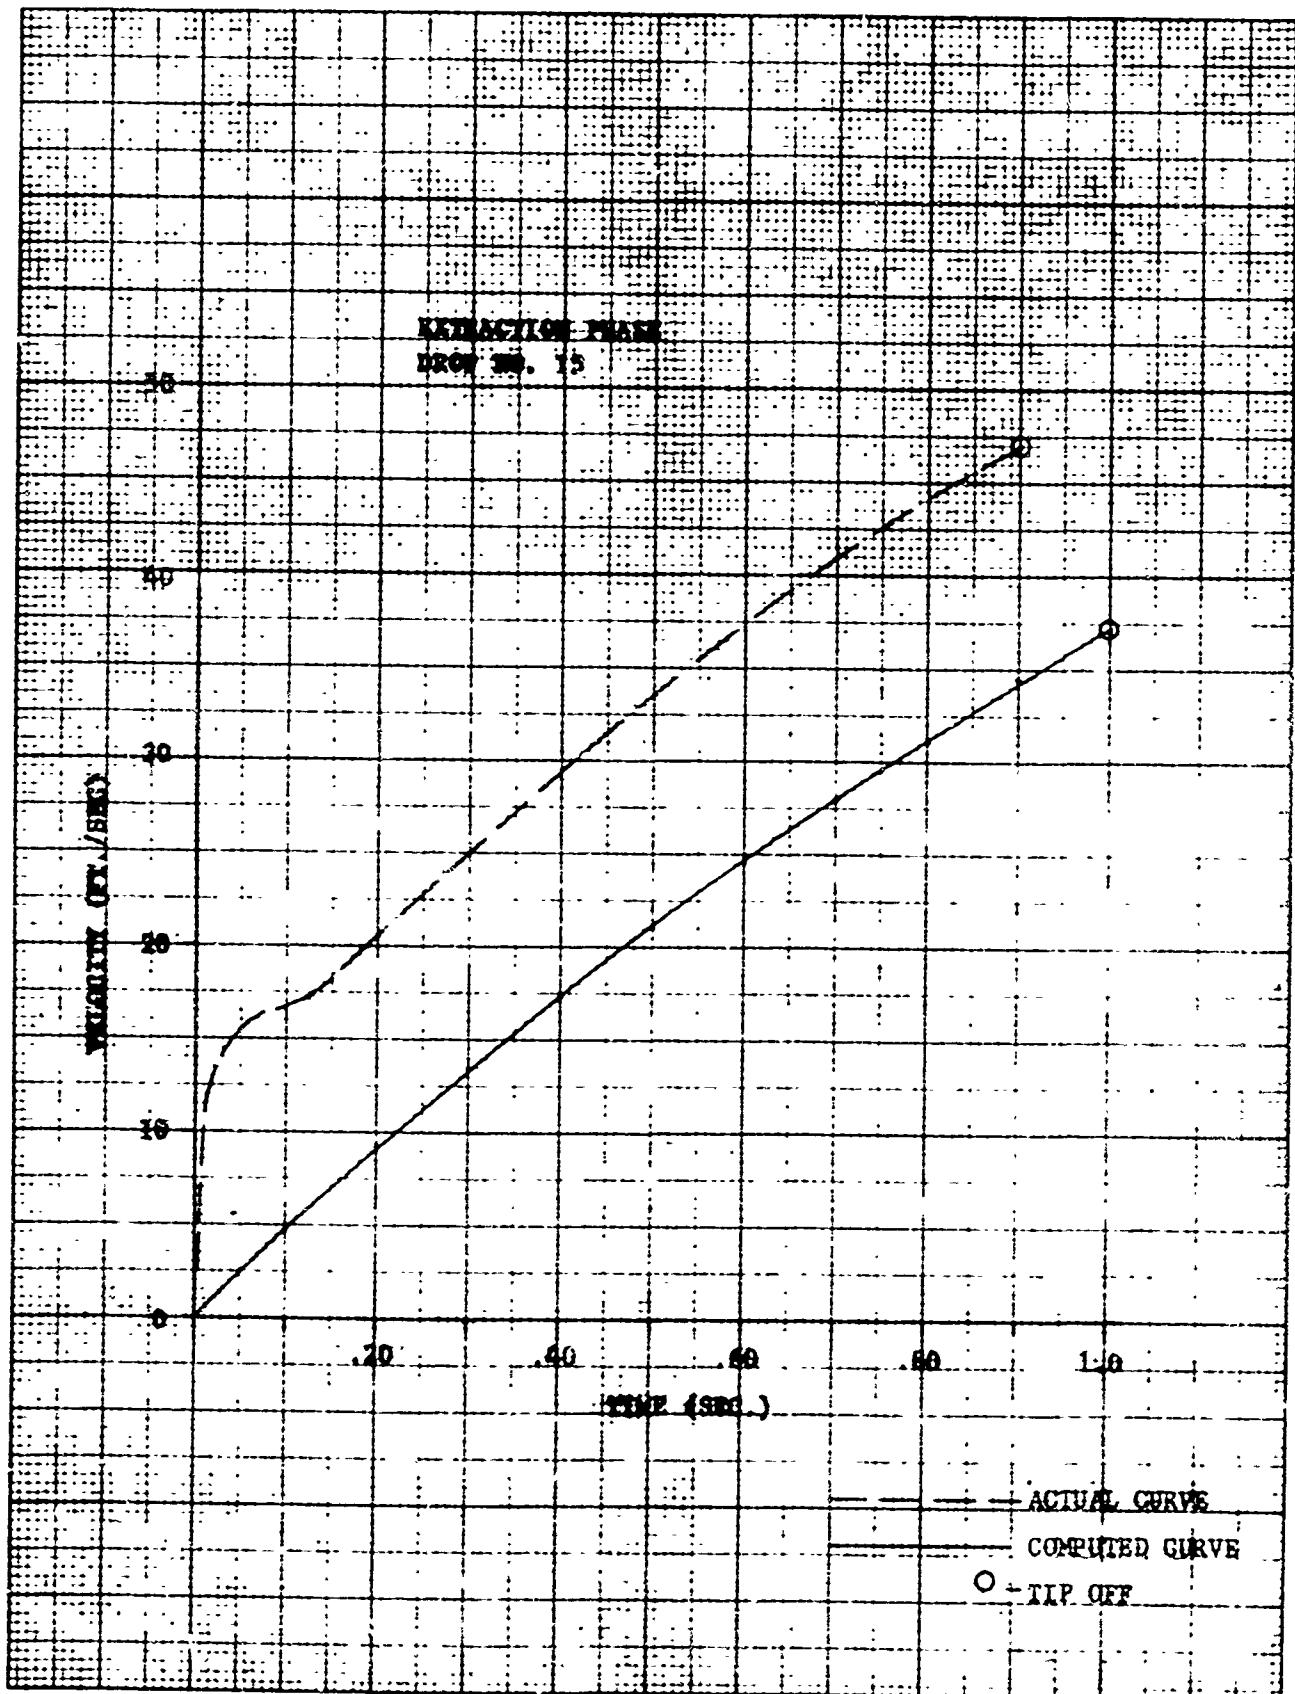

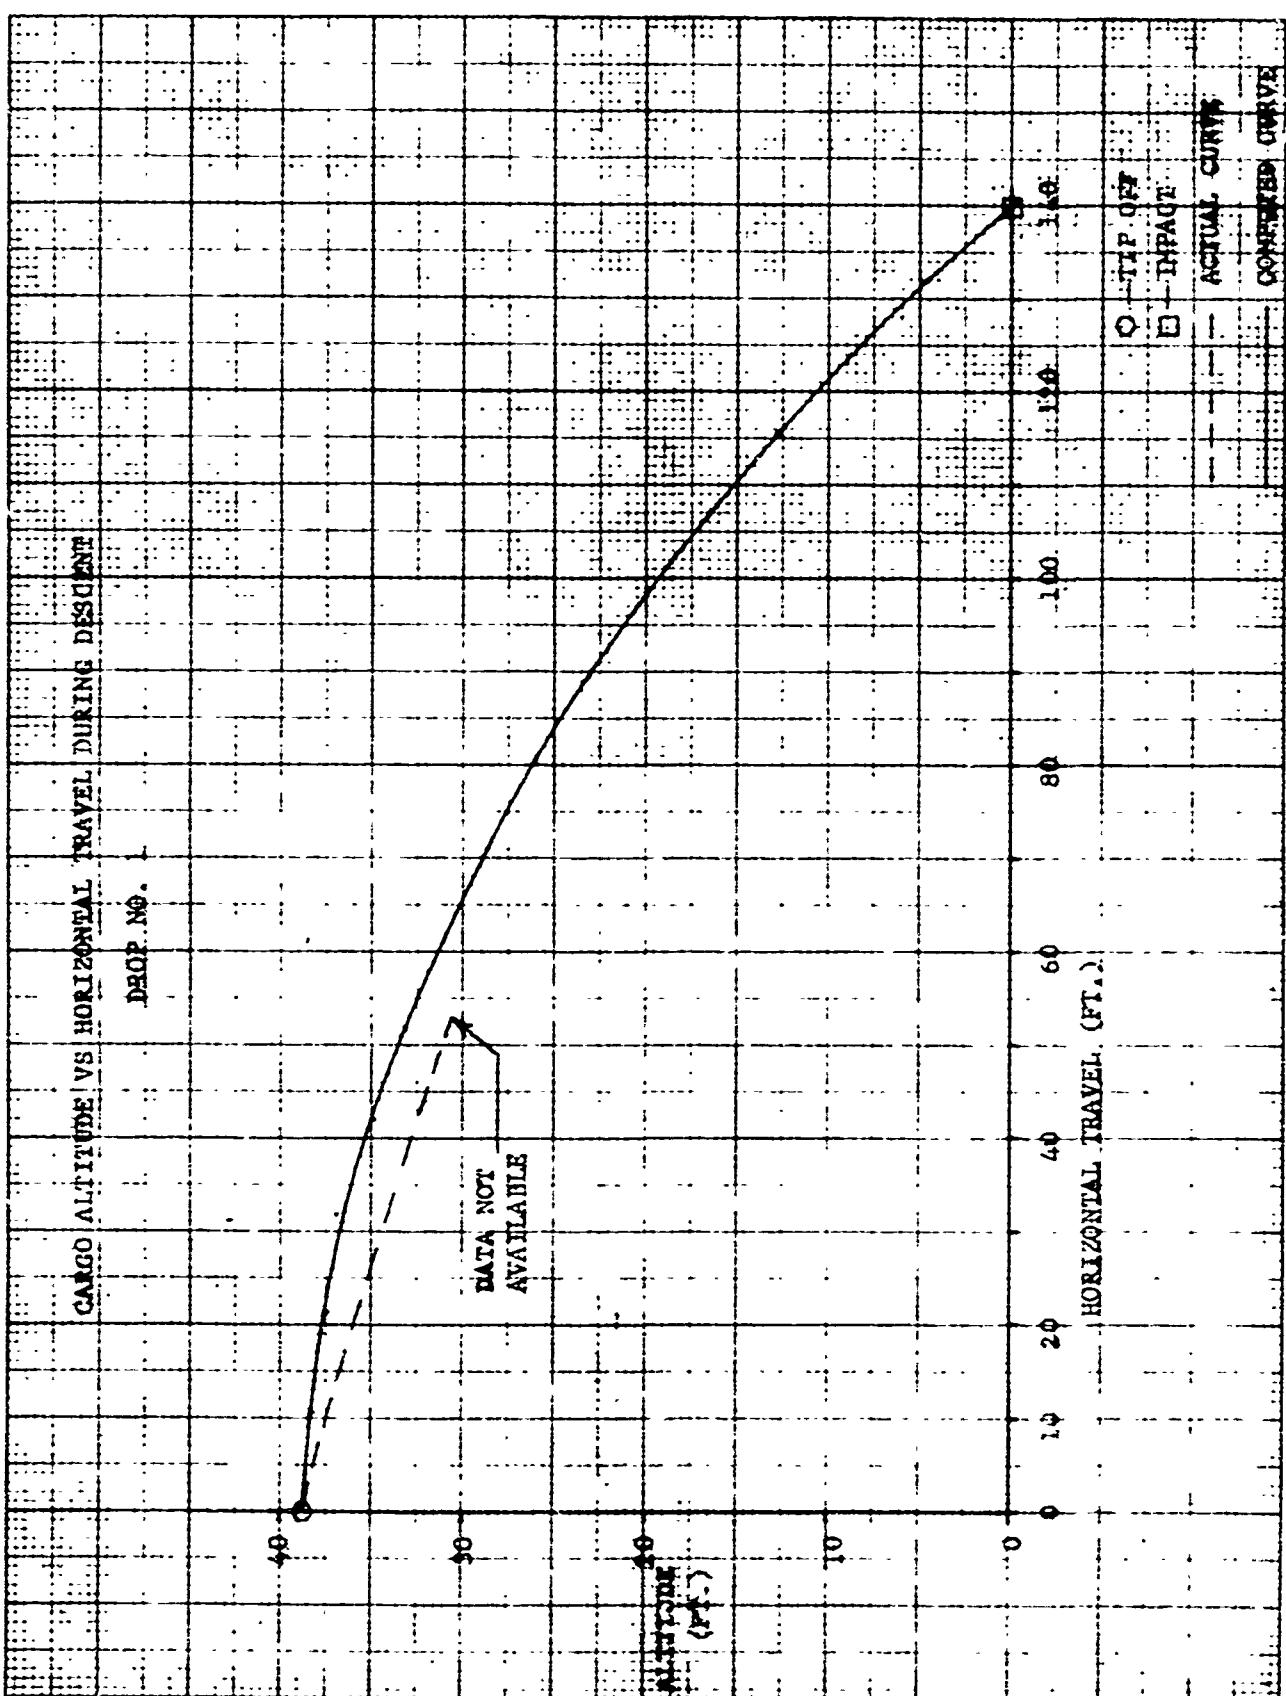

Figure 19

As can be seen, the slopes of these curves are quite similar which indicates the actual "g" loads are close to the predicted, however, the amplitudes for a given time are noticeably different. This is one of the cases indicated earlier when the equations of motion are not capable of predicting actual occurrences. The computer equations assume a rigid non-flexible member between the load and the parachute; thus, theoretically, the load is subjected to the exact force-time output of the parachute which decays proportionally to the decay of the V^2 term. This results in a velocity-time curve which is relatively smooth as shown in the figures. However, in the real case the connecting member, being nylon webbing, is quite flexible and can store some energy prior to load movement. Therefore, at load movement, which is some predetermined time during the inflation period, the load is subjected to force levels for a short time that are higher than predicted. This gives a cargo jerk which results in an initial steep slope on the velocity-time curve with a larger amplitude than would be obtained for the theoretical case.

C. Descent Phase

Cargo motion during the descent phase was recorded by high-speed motion picture cameras. The film was then reduced using a motion analyzer to various useful curves. Plots were made of each individual test showing the actual curve and the curve predicted by the computer. All curves start at the beginning of the descent phase and run to ground impact. Figures 20 through 33 present the plots of cargo altitude versus horizontal travel. Plots of Drops No. 1, 3, 8 and 11 are incomplete due to the inability to acquire sufficient film data.

A second curve was generated from the data obtained on each test. This curve was a plot of horizontal travel versus descent time. Comparative curves were obtained from the computer analysis and are shown in Figures 34-47. Again Drop No. 1, 3, 8 and 11 are incomplete due to lack of data.

The third plot used in comparing the computer analysis against actual tests is shown below in Figures 48 through 61. These are plots of cargo pitch angle versus descent time. Drops Nos. 1, 3, 8 and 11 are not complete because sufficient data was not acquired from these tests.

In several of the tests, as shown by the curves, the actual cargo pitch angle is quite different from the predicted angle. In the tests the aircraft is pitching, due to turbulence and aircraft instability and this induces ~~some~~ angular acceleration to the cargo. One assumption in the computer equations is that the aircraft does not change pitch angle during extraction.

In figures 76 through 89 cargo pitch angle was plotted versus drop altitude. In these curves the effect of aircraft induced angular acceleration can also be observed.

In Figures 76 through 89 plots of predicted cargo horizontal velocity versus descent time are given. Due to the inaccuracies of graphically integrating distance-versus-time data, the actual velocity-versus-time plots are not given since the comparison would be misleading. However, since such close agreement was witnessed between the actual and predicted curves of horizontal travel versus descent time, it can be stated that the actual curves of horizontal velocity versus descent time will be in close agreement with the predicted curves.

D. Impact Phase

The equations for this phase are much less descriptive of the actual motion than are the equations for the drop phase. Too many variables are not and cannot be considered in the computer program. The slide length seems to be the only method of comparing the computer analysis against the actual occurrence for the impact phase. Below is a tabulation of slide lengths.

Test No.	Slide Length	
	Actual	Computer
1.	Load Overturn	116.8
3.	65	73.32
4.	60	102.08
5.	80	90.67
6.	90	138.85
7.	Load Overturn	105.23
8.	72	77.07
9.	60	76.46
10.	Load Overturn	104.39
11.	90	117.63
12.	90	154.28
13.	110	131.29
14.	110	100.61
15.	160	85.76

A value for the coefficient of friction was extremely difficult to select. Below is a list of variables that effect the coefficient of friction.

1. Impact Zone Terrain
2. Impact Zone Vegetation
3. Impact Zone Moisture Content

AIRCRAFT ARMAMENT'S, Inc.

4. Impact Zone Hardness
5. Impact Zone Material
6. Load Platform Material
7. Load Impact Angle.

The instantaneous value of the coefficient of friction changes all along the slide path in the actual situation. Whereas, the computer assumes the instantaneous coefficient value is equal to the average value. With this though that the exact coefficient of friction value is nearly impossible to obtain, one can say that the two comparative slide lengths are in close agreement.

III. COMPUTER PROGRAM

A. General

When the computer program was set up for use on AAI's computer it was necessary to rewrite the program in three distinct separate phases due to the size of AAI's computer. The new program along with its inputs is presented in this section. Also included is a listing of the numerical values of the input as obtained from the test program.

B. Nomenclature

Presented below is the program input nomenclature. It was felt that clarification was needed as far as defining the coordinate system of each individual computer input.

<u>Nomenclature</u>	<u>Units</u>	<u>Definition</u>
t_0	sec	Extraction start time
ψ_0	degrees	Initial yaw angle of cargo in ground fixed frame of reference
r_{x_0}	feet	x component of distance from wind fixed frame of reference to cargo c.g.
r_{y_0}	feet	y component of distance from wind fixed frame of reference to cargo c.g.
r_{x_0}	ft/sec	$\frac{d r_{x_0}}{dt}$
r_{y_0}	ft/sec	$\frac{d r_{y_0}}{dt}$

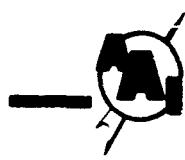

AIRCRAFT ARMAMENTS, Inc.

Nomenclature	Units	Definition
L_y_o	feet	y component from parachute C.G. to extraction point in ground fixed frame of reference.
L_z_o	feet	z component from parachute C.G. to extraction point in ground fixed frame of reference.
\dot{L}_y_o	ft/sec	$\frac{d L_y_o}{dt}$
\dot{L}_z_o	ft/sec	$\frac{d L_z_o}{dt}$
ψ_a	degree	Pitch angle of aircraft in ground fixed frame of reference
φ_a	degree	Roll angle of aircraft in ground fixed frame of reference
γ_a	degree	Yaw angle of aircraft in ground fixed frame of reference
r_{ax_o}	feet	x distance from ground fixed frame of reference to aircraft C.G.
r_{ay_o}	feet	y distance from ground fixed frame of reference to aircraft C.G.
r_{az_o}	feet	z distance from ground fixed frame of reference to aircraft C.G.
Δt_1	second	Time increment for extraction phase
Δt_2	second	Time increment for tip-off phase
Δt_3	second	Time increment for descent phase
a	feet	x distance from cargo c.g. to extraction point in cargo frame of reference
b	feet	y distance from cargo c.g. to extraction point in cargo frame of reference

AIRCRAFT ARMAMENTS, INC.

Nomenclature	Units	Definition
c	feet	z distance from cargo c.g. to extraction point in cargo frame of reference.
d	feet	x distance from cargo c.g. to center of the platform floor in cargo frame of reference
e	feet	y distance from cargo c.g. to center of the platform floor in cargo frame of reference
f	feet	z distance from cargo c.g. to center of the platform floor in cargo frame of reference
n	feet	z distance from aircraft c.g. to reaction point in aircraft frame of reference
m	slugs	Mass of cargo
M	slugs	Mass of parachute
I_{xx}	slug-ft ²	Moment of inertia of the cargo about its x axis
I_{yy}	slug-ft ²	Moment of inertia of the cargo about its y axis
I_{zz}	slug-ft ²	Moment of inertia of the cargo about its z axis
V_x	ft/sec	x component of wind velocity in the ground fixed frame of reference
V_y	ft/sec	y component of wind velocity in the ground fixed frame of reference
V_z	ft/sec	z component of wind velocity in the ground fixed frame of reference
V_{ax}	ft/sec	x component of aircraft velocity in the wind fixed frame of reference
V_{ay}	ft/sec	y component of aircraft velocity in the wind fixed frame of reference

AIRCRAFT ARMAMENTS, Inc.

PAGE NO. D-101

REPORT NO. ER-3841

Nomenclature	Units	Definition
v_{az}	ft/sec	z component of aircraft velocity in the wind fixed frame of reference
d_e	feet	x component from cargo c.g. position, before extraction, to the tip of the aircraft ramp in the aircraft frame of reference.
l_c	feet	Half length of platform
$K_L \alpha$	slug/ft. rad.	Slope of the K_L versus α (angle of attack) curve
K_{D_0}	slug/ft.	Cargo drag factor with $\alpha = 0$
K_{D_2}	slug/ft. rad.	Slope of K_D versus α^2 curve
Z_{test}	feet	Altitude test for descent phase
$(C_D A)_0$	ft ²	Product of drag coefficient and inflated parachute drag area
Diam.	ft.	Skirt diameter of inflated parachute
G_N	--	Number of parachutes used
G_F	--	Cluster factor
ρ_0	slug/ft ³	Air density at the extraction altitude

IMPACT PHASE INPUT NOMENCLATURE

<u>Nomenclature</u>	<u>Units</u>	<u>Definition</u>
t_0	second	starting time
Δt	second	time increment for numerical integration
x_0	feet	x component of cargo position in ground fixed frame of reference
\dot{x}_0	ft/sec	$(\frac{dx}{dt})_0$
ψ_0	radians	Pitch angle of cargo in ground fixed frame of reference
$\dot{\psi}_0$	rad/sec	$(\frac{d\psi}{dt})_0$
L_{x_0}	feet	X component of parachute line length in ground fixed frame of reference
\dot{L}_{x_0}	ft/sec	$(\frac{dL_x}{dt})_0$
v_x	ft/sec	X component of wind velocity in ground fixed frame of reference
v_z	ft/sec	Z component of wind velocity in ground fixed frame of reference
ALT	feet	Z component from aircraft C.G. to ground fixed frame of reference
K_{11}	feet	X component from cargo C.G. to attachment point of external decelerator in cargo frame of reference
K_{13}	feet	Z component from cargo C.G. to attachment point of external decelerator in cargo frame of reference
a	feet	X component from cargo C.G. to extraction point on cargo frame of reference
c	feet	Z component from cargo C.G. to extraction point in cargo frame of reference

<u>Nomenclature</u>	<u>Units</u>	<u>Definition</u>
d	feet	X component from cargo C.G. to platform centerline in cargo frame of reference
f	feet	Z component from cargo C.G. to platform floor in cargo frame of reference
l_c	feet	half length of the platform
I_{yy}	slug-ft ²	Moment of inertia of the cargo about its y axis
K_f	slug/ft	Parachute drag factor
m	slugs	mass of cargo
M	slugs	mass of parachute
CN		Case number
θ_{max}	radians	critical pitch angle for which pitch will occur
Dia. Chute	feet	inflated parachute diameter
..		coefficient of friction
..	feet	line length
z_o	ft/sec	vertical impact velocity
\ddot{x}_o	ft/sec ²	$(\frac{d^2x}{dt^2})_o$
f	pounds	magnitude of external force

TABLE II

D. Lateral Restraint

It was originally thought that the pilot would fly the aircraft in a crabbed position during a crosswind situation. In this position he would have lined the aircraft up with its velocity vector in the wind fixed frame of reference. The extraction parachute in this case would be directly behind the aircraft, because the parachute always lines up with the aircraft velocity vector in the wind fixed frame of reference. Taking this into consideration, the computer program was written excluding a lateral movement restraint requirement in the extraction phase. Such a restraint, of course, is unnecessary when the extraction parachute is directly behind the load.

Due to the difficulty encountered in trying to maintain a stable attitude while flying the aircraft in a crosswind situation, the actual cases proved to be different. When only a few feet above the ground the pilot was concerned primarily with motion in the direction that would result in ground contact, i.e., pitch angle change and vertical motion; therefore, the aircraft was usually not lined up with the resultant velocity vector. The parachute in this case would not be directly behind the aircraft, but would be off to one side. How extreme the parachute is off to one side depends on the magnitude of the angular difference between the actual aircraft heading vector and the velocity vector of the aircraft in the wind fixed frame of reference. Lack of a lateral restraint in the extraction phase of the computer program will allow the load to exceed the lateral boundaries of the aircraft when acted upon by some side force. The side force in this case is the lateral component of the extraction force produced by the misaligned parachute. In actuality the load cannot exceed the aircraft lateral boundaries; thus an error could be produced in the

computer results without this restraint. To add this restraint requirement to the computer program would mean a major change to the program. It was found that the error this caused could be minimized by forcing certain inputs to be particular values in the tip-off phase. The two inputs that were changed were the yaw angle (γ) and the lateral position vector (r_y). These two quantities were given values they would have at tip-off if the load were laterally restrained by the aircraft.

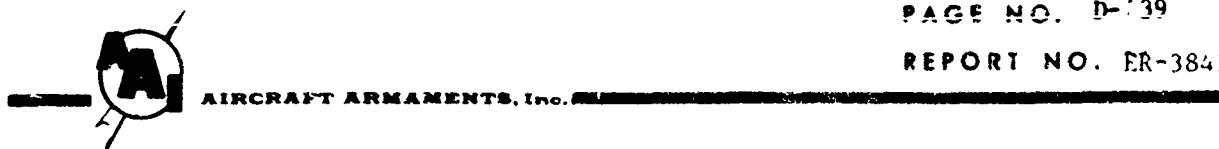

IV. CONCLUSIONS AND RECOMMENDATIONS

Included in this section are the changes, deletions, and revisions to the Phase I report. Major changes, deletions, and revisions are not necessary due to the close agreement of the results from the computer analysis when compared to the actual occurrence. There are a few minor changes that will further refine the analysis if incorporated. The following changes and revisions should be incorporated in the Phase I Report.

The limits of the extraction point locations with respect to the cargo C.G. in both the vertical and lateral direction should be changed. These changes are as follows: Vertical distance from G.C. to be within \pm 10 inches and -5 inches. Lateral distance from C.G. to be within \pm 5 inches. The lateral limitation was decreased because the cargo could become jammed in the cargo compartment and cause aircraft damage, when the lateral offset distance was too large.

The longitudinal limitation in the location of the C.G. from the center of a 9 foot platform can be changed from \pm 6 inches to \pm 10 inches. The maximum offset was not found during the testing program but the load did survive with a \pm 10 inch offset.

The limitation of the 12 knot crosswind is not a product caused by system operation as originally thought. Instead, this limit is influenced mainly by the ability of the pilot to manipulate the aircraft in excessive crosswind. Since the aircraft flies very close to the ground, it is effected by the ground turbulence. This turbulence causes the aircraft to move quite erratically and almost impossible to control. Aircraft dipping and lifting

10 feet is common with ground turbulence caused by a 12 knot wind. Thus, in most cases the pilot will fly the aircraft 20 feet or higher above the ground with a crosswind of 12 knots or more. This drop altitude will cause cargo damage for excessive impact forces.

Sufficient data was not acquired to state whether the limits on the impact angle are maximum. However in test no. 14 the load impacted at a 14° tail down angle with load survival.

As the load descends, it oscillates. For loads that are alike, the oscillations will be identical. Therefore, the impact angle is dependent on the altitude for any load. Further investigation is needed in this area to more closely identify specific load properties with oscillatory motion. This in turn will also increase load survivability.

At this time there have been no tests of multiple load delivery using the ground slide system. It is recommended that efforts be directed in this area to gain this much needed knowledge.

On all except one of these tests, the cargo was restrained to the platform by use of chains. These were used so that the load would not shift at all during the testing. Of course, in an actual air delivery situation regular restraint straps are used. The information acquired from the tests can be applied to an air delivery situation, in that the shifting limitations are described.

A special platform is needed that will resist overturn, withstand the forces exerted upon it at ground impact, and prohibit bending in the longitudinal direction. This platform will basically have a rounded front edge and heavy rails that run longitudinally. The platform used in the test phase had these physical qualities, but it was over designed. During the testing the only part of the platform that seemed to show any failure was the bottom surface. This failure only appears on the platforms that have wooden panels. The design of the new platform should have as its goals: low cost, light weight, bending resistance in rails, and overturn resistance.

Addendum to technical report, 69- AD, (ER-3841), January 1965, contract No. DA19- 129-AMC-337(X), U. S. Army Natick Labs.		US Army Natick Laboratories Natick, Massachusetts 01760	

13. ABSTRACT

This report is a continuation of the Phase I Report of the Ground Slide Airdrop Study conducted under Contract No. DA19-129-AMC-337(X). The object of the report is to present the findings of the Exploratory Test Phase, Phase II, and to compare the actual findings to those predicted by the Phase I study.

Results of limited flight tests conducted at Ft. Bragg, North Carolina are presented and compared to analytical results which were generated using test conditions as input values. In general, the test values and the computed values are in close agreement.

Also included are all changes, deletions and revisions to be incorporated in the preliminary design specifications of the Phase I report.

1. This document contains neither recommendations nor conclusions of the Defense Department. It has been reviewed and approved for public release by the Defense Department.
